The exfoliation of the primary teeth and eruption of permanent teeth is a normal physiological event through growth and development process. Caries lesion and early extraction is commonly seen in first permanent molar teeth. Early extraction can cause primer contacts, occlusal disorders, shifts in the lower jaw and thus may lead to temporomandibular joint problems.

When a permanent first molar teeth shooting, many factors should be considered, and if necessary a multidisciplinary approach to the treatment plan should be done carefully. Clinical practice and patient cooperation in determining the medical, dental,
social and should be evaluated together with the stories.

This review includes guidance of the patient in case of early molar loss and affects of early loss of the first molar teeth.
